NIOH Report 17/2011

http://www.nioh.ac.za/publications/publications\_pathaut\_reports.htm

### ACKNOWLEDGEMENTS

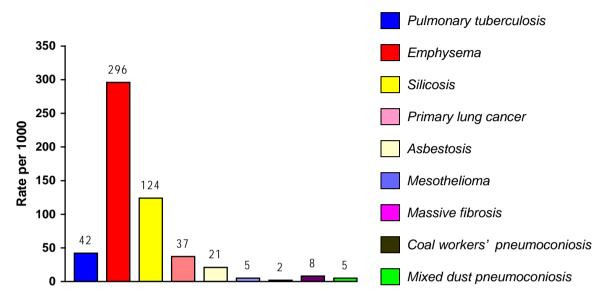

We thank all the staff members of the NIOH Pathology Department, for their invaluable contribution to the autopsy service.

We also thank Prof Tony Davies for editing the manuscript.

National Institute for Occupational Health, PO Box 4788, Johannesburg, 2000, South Africa ISSN 1812-7681

### **EXECUTIVE SUMMARY**

During 1984, 3 092 cases came to autopsy at the NIOH. Of these, 63.6% were black men, 35.5% were white and 0.9% were coloured.

Overall disease rates (per 1000 autopsies) for 1984 are shown in Figure 1.

### GLOSSARY

Asbestosis	Lung fibrosis caused by asbestos fibres
Coal workers' pneumoconiosis	Lung fibrosis caused by exposure to coal dust
Emphysema	Lung disease caused by the destruction of the alveolar walls
Massive fibrosis	Lung fibrosis caused by exposure to dust and measuring more than 1 cm in diameter
Mesothelioma	A malignant tumour of the pleural cavity of the lungs
Miner	A person who has worked in a controlled mine or works
Mixed exposures	The multiple dust types to which a miner may be exposed, having worked in several mining commodities in his lifetime
Prevalence	The number of cases in a defined population at a given time
Silicosis	Lung fibrosis caused by inhalation of silica dust; detected by the presence of silicotic nodules in the lung tissue
Surveillance	The ongoing and systematic collection, analysis and interpretation of data related to adverse health outcomes

The Occupational Diseases in Mines and Works Act, 1973 (Act 78 of 1973) requires that the cardiorespiratory organs of a deceased person who has worked at a controlled mine or a controlled works be examined for the presence of occupational disease, regardless of the clinical cause of death and provided that the next of kin agrees. These examinations are performed by pathologists at the National Institute for Occupational Health (NIOH). A detailed report on each case examined is sent to the Medical Bureau for Occupational Diseases (MBOD). Cases certified as having a compensable disease are then referred to the Compensation Commissioner's office, where the payment for compensation is managed.

Since 1975, the pathological findings from the autopsy examinations have been recorded on the computerised PATHAUT database. PATHAUT comprises data from autopsy examinations and clinical files which include occupational histories. The database is unique and provides an important resource for both surveillance and research. These data are the only comprehensive surveillance data on occupational lung disease in the South African mining industry.

The data presented in this report summarise the PATHAUT system surveillance results, i.e. the results of the systematic collection, collation, and analysis of the pathology findings in the cardiorespiratory organs of mine workers. Data from PATHAUT are exported into, and analysed, using SAS v9.1.

This report describes autopsy cases examined during the year 1984. This and other annual reports can be accessed at <u>www.nioh.ac.za</u>.

Many of the cases had "mixed" exposures in that they had been employed in more than one commodity. For simplicity, cases are categorised according to the commodity in which most years of service were recorded, i.e. the commodity in which the miners had worked for the longest period.

All disease rates reported in this document are expressed per 1000. In all calculations, the denominators used are the total numbers of autopsies in specific commodities, age groups or population groups. Some of these rates must be viewed with caution, as the denominators are very small. This applies, for example, to those commodities where few workers are employed (such as manganese mining), and to the older age groups in some instances.

1

The number of autopsies performed for 1984 is presented in Table 2-1.

## TABLE 2-1DISTRIBUTION OF AUTOPSIES BY YEAR AND POPULATION GROUP<br/>(1984)

Year of autopsy	Bla N	ack %	Wh N	nite %	Colo N	oured %	Unkr N	nown %	Total N
1975	2 190	71	854	28	32	1			3 076

Total	22 160	66	10 981	33	361	1	1		33 503

It is important to note that a referral bias exists: there is a low autopsy rate for black men who have left employment at the mines, whereas the majority of white retired miners come to autopsy.

The pathologists at the NIOH perform two types of autopsy examinations. For men dying distant from Johannesburg, the cardio-respiratory organs are removed locally, preserved in formalin and sent to the NIOH. Full autopsies are undertaken on men who die close to Johannesburg.

Table 2-2 shows the distribution of autopsies by population group for 1984. Autopsies of only the cardio-respiratory organs comprised 83.2% of all examinations.

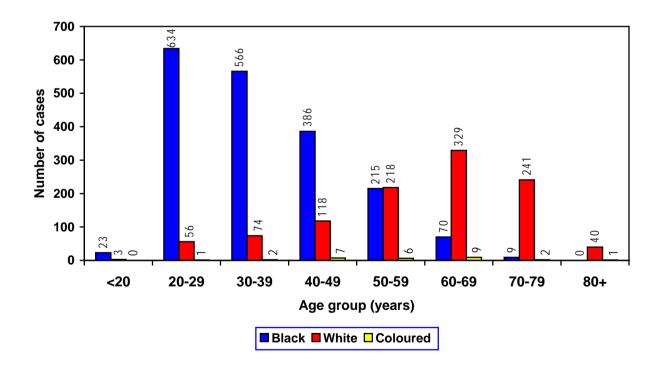

## TABLE 2-2NUMBER AND PROPORTION OF AUTOPSIES BY TYPE AND<br/>POPULATION GROUP (1984)

	Black		White		Coloured		Total	
Autopsy type	Ν	%	Ν	%	Ν	%	Ν	%

TABLE 2-3NUMBER AND PROPORTION OF AUTOPSIES BY AGE AND<br/>POPULATION GROUP (1984)

### FIG 2-1 DISTRIBUTION OF AUTOPSIES BY AGE AND POPULATION GROUP (1984)

Cases were placed in categories according to the commodity in which they had worked for the longest duration (most exposure). Many men worked in a number of different mining commodities

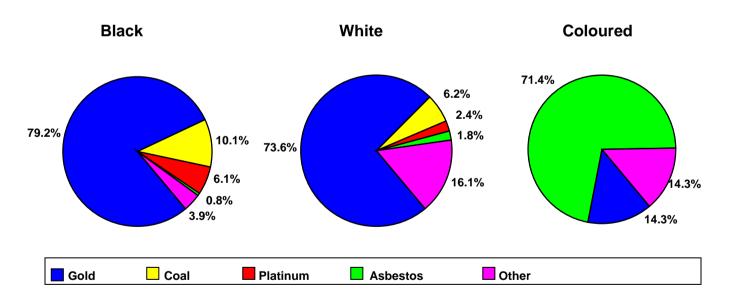

during their lifetimes and had "mixed" exposures. This was not taken into account in the analysis of exposure type (commodity).

Table 2-4 and Figure 2-2 show the distribution of autopsies by commodity and population group for 1984.

Commodity	Black		Wh	ite	Colo	ured	Total	
Commodity	Ν	%	Ν	%	Ν	%	Ν	%

The distribution of active tuberculosis (TB) by anatomical site is presented in Figure 3-1 (n=172). Active pulmonary TB (PTB) was diagnosed in 4.2% (n=130) of all cases autopsied in 1984. Most of the men with PTB were black (85.4%; 111 cases), 12.3% (16 cases) were white and 2.3% (3 cases) were coloured.

### FIG 3-1 DISTRIBUTION OF ACTIVE TB BY SITE (1984)

The distribution of active PTB cases by commodity is shown in Table 3-1. The rates in this and subsequent tables and figures are expressed per 1000. The majority of active PTB cases (53.4%) came from the gold mining industry (71.4% of all autopsy cases came from that commodity).

Commodity	Bla	ack	White		Colo	ured	Total

Silicotic nodules were found in the lungs of 391 cases (12.6% of all autopsies), 91.0% of which came from the gold mining industry. Of all cases of silicosis, occasional silicotic nodules were found in 48.8% of cases, a few in 26.5%, a moderate number in 18.4% and a large number in 6.2%.

The distribution of cases with silicosis by commodity and population group is presented in Table *4*-1.

## TABLE 4-1NUMBER OF CASES AND PREVALENCE OF SILICOSIS BY COMMODITY<br/>AND POPULATION GROUP (1984)

# TABLE 4-3NUMBER OF CASES AND PREVALENCE OF SILICOSIS IN THE GOLD<br/>MINING INDUSTRY, BY YEARS OF SERVICE AND POPULATION<br/>GROUP (1984)

### **MASSIVE FIBROSIS**

There were 5 (0.2%) cases of massive fibrosis (3 black, 2 white). Four cases of massive fibrosis were from the gold mining industry. The remaining case was from the coal mining industry.

### COAL WORKERS' PNEUMOCONIOSIS

There were 25 (0.8%) cases of coal workers' pneumoconiosis of which 23 cases were known to be from the coal mining industry. The remaining 2 cases were from the gold mining industry.

### MIXED DUST PNEUMOCONIOSIS

There were 17 (0.5%) cases of mixed dust pneumoconiosis. These cases came from the gold (n=12), coal (n=2), copper (1) and diamond (1) mining industries. In one case the industry was not stated.

### ASBESTOSIS AND PLEURAL PLAQUES

There were 66 cases of asbestosis of which 81.8% (n=54) had slight, 13.6% (n=9) moderate and 4.5% (n=3) marked fibrosis. Of these, 36 (54.5%) had worked in the asbestos mining industry at some time in their lives. There were 13 cases that had asbestos plaques and 7 (53.8%) of these had asbestosis. Note that the parietal pleura (the site where plaque formation usually occurs) is seldom submitted with the lungs.

The distribution of asbestosis by age and population group is shown in Table 5-1.

One hundred and thirteen cases of primary lung cancer were found at autopsy, 19.5% of which were in black, 79.6% in white and 0.9% in coloured men. Most of the cases were small cell lung carcinomas (40.7%; n=46), followed by squamous lung carcinomas (29.2%; n=33), adeno carcinomas (15.0%; n=17), large cell lung carcinomas (10.6%; n=12) and broncho-alveolar carcinomas (4.4%; n=5)

The distribution of primary lung cancer by age and population group is presented in Table 8-1.

### **SECTION 9 – CLINICAL CAUSES OF DEATH**

Table 9-1 and Figure 9-1 show the clinical causes of death as stated in the accompanying documents submitted with the cardio-respiratory organs, by population group. Diseases of the cardio-vascular system were the most frequent (11.1%) overall. Black men had the highest proportion of unnatural causes of death (64.2%). In 20.7% of all cases, the cause of death was not stated.

System	Black		Wh	nite	Colo	ured	Total
